This paper presents LLM-jp-4, a family of Japanese sovereign large language models (LLMs) developed with an emphasis on transparency, reproducibility, and practical usability. LLM-jp-4 comprises an 8B dense model and a 32B-A3B mixture-of-experts model, both trained from scratch on approximately 12 trillion tokens. To support independent verification and reproduction, we establish explicit criteria for selecting training data, external models, and software, and make the development process publicly available. Evaluation results demonstrate substantial improvements over previous LLM-jp models and competitive performance against open-weight models of similar scale. By documenting the development principles, training procedures, and empirical findings of LLM-jp-4, we aim to provide a reference for future sovereign AI development.

1. Introduction

Despite the growing importance of large language models (LLMs), their development is concentrated in a small number of companies and regions, and the full development process is not publicly disclosed for many state-of-the-art models (Wan et al. 2025; Sajadieh et al. 2026). The concentration and closed nature of LLM development create problems for societal autonomy and scientific understanding. First, dependence on specific external LLM developers may limit the ability of countries and regions to develop and operate AI systems that meet their own linguistic and social needs. The idea of maintaining such autonomy has been discussed under the concept of sovereign AI (Bondarenko et al. 2025). Second, keeping the development process internal to a limited number of LLM developers makes it difficult for outside researchers to analyze and verify how the capabilities, limitations, and potential risks of these models arise. This problem extends beyond any particular country or region, hindering the broader research community's efforts to develop a scientific understanding of AI.

We address these problems by developing LLMs from scratch and making the entire development process public. The performance and behavior of an LLM are shaped throughout development, including training data, data processing, training objectives, and optimization methods. Releasing the final model weights alone is insufficient for

* LLM-jp-4 was a team effort. Authors sorted alphabetically. Contribution statements can be found in Appendix.

fully understanding how the model's capabilities and properties emerge. Making the entire development process public enables third parties to verify, reproduce, and compare results (Biderman et al. 2023; Groeneveld et al. 2024; Apertus et al. 2025). This openness provides a foundation for sovereign AI by enabling anyone to use, analyze, and further develop models while advancing scientific understanding of how training shapes their capabilities, biases, and safety properties.

This paper introduces LLM-jp-4, a family of LLMs developed to provide an open foundation for both sovereign AI in Japan and scientific research on LLMs worldwide. In addition to the final model weights, we make the entire training process publicly available in a form that enables independent verification and reproduction. To this end, we established strict selection criteria for the data, external models, and code used in training, taking into account legal and licensing requirements, as well as the feasibility of independent verification and reproduction. The LLM-jp-4 family comprises an 8B dense model and a 32B-A3B mixture-of-experts (MoE) model. Each model was trained from scratch on approximately 12 trillion tokens in total (Figure 1). Our evaluations show that LLM-jp-4 substantially outperforms the previous generation of LLM-jp models and achieves performance comparable to strong open-weight LLMs on Japanese benchmarks.

In the following sections, we first describe the development principles of LLM-jp-4 and then present the training data, model architecture, training procedure, and evaluation results. We explain how technical choices throughout development balance the goal of improving model performance with requirements for transparency, reproducibility, and legal compliance. The LLM-jp-4 models are publicly available on Hugging Face under the Apache 2.0 license.[1]

2. Development Principles

Transparency and reproducibility are key principles in the development of LLM-jp-4. These principles are essential for supporting independent LLM development in Japan and for providing a foundation that enables third parties to verify the development process and build on it through further research and development.

For this purpose, LLM-jp-4 requires that the development process remain reproducible by third parties when selecting data, external models, and software. Specifically, we limit these resources to those that are available to third parties or for which third parties can construct equivalent resources based on publicly available information about their sources, acquisition methods, processing procedures, and other relevant details. These selection criteria are designed to satisfy legal requirements, including Japanese copyright law, and to be consistent with the Open Source AI Definition (OSAID) published by the Open Source Initiative[2][3].

2.1 Dataset Selection Criteria

We apply the reproducibility and legal compliance requirements described above to all datasets used for training LLM-jp-4. In addition, we require that not only our use of a dataset but also its original construction process comply with applicable legal and licensing requirements, including Japanese copyright law.

2 https://opensource.org/
3 https://opensource.org/ai/open-source-ai-definition

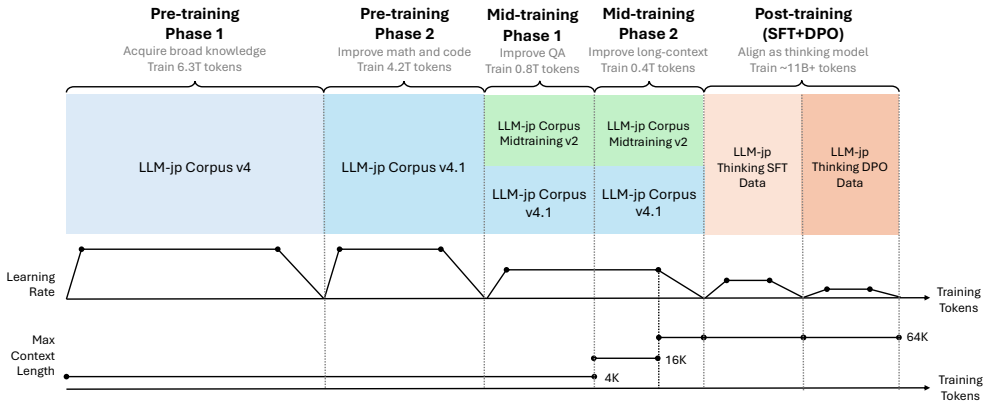

Figure 1: Overview of the training pipeline of LLM-jp-4. Training proceeds through three stages: pre-training, mid-training, and post-training. Pre-training uses LLM-jp Corpus v4 to acquire broad knowledge (Phase 1; 6.3T tokens), followed by LLM-jp Corpus v4.1 with increased proportions of math and code (Phase 2; 4.2T tokens). Mid-training mixes LLM-jp Corpus Midtraining v2 with the pre-training corpus to improve question-answering capabilities (Phase 1; 0.8T tokens) and extend the maximum context length from 4K to 64K tokens via 16K (Phase 2; 0.4T tokens). Post-training aligns the models as thinking models through SFT and DPO. The bottom panels show the learning-rate schedule and maximum context length throughout training.

Table 1: Release levels used to manage the permitted uses of datasets in LLM-jp-4. Internal-model training denotes training models used only for internal experiments, whereas public-model training denotes training models intended for public release. Retrieval denotes use in a search or retrieval system in which portions of the dataset may be presented to users as retrieval results. Redistribution denotes redistribution of the dataset itself by LLM-jp. A check mark indicates that the corresponding use is permitted.

Level	Internal-model training	Public-model training	Retrieval	Redistribution
L1	✓	✓	✓	✓
L2	✓	✓	✓	✗
L3	✓	✓	✗	✗
LX	✓	✗	✗	✗
LZ	✗	✗	✗	✗

LLM-jp assigns a release level to each dataset subset to explicitly manage the scope in which it can be used. The release level consists of five levels, as shown in Table 1. For training the publicly released LLM-jp-4 models, we use only data classified as L1 through L3, which permits use for public model training.

2.2 Criteria for External Models

LLM-jp also considers the licenses and terms of use of external machine learning models that are used to construct training data or have already been used in the data construction process. In LLM development, machine learning models are commonly used to select,

process, or generate training data. The terms governing the use of such models may affect the conditions under which the resulting datasets and the models trained on them can be released.

For this reason, LLM-jp constructs training data using only machine learning models released under open-source licenses whose terms are compatible with our intended release conditions for models and data. We exclude models whose terms prohibit the use of their outputs to train competing models or impose additional restrictions on the release or distribution of downstream models. Examples include OpenAI's proprietary GPT models, Anthropic's Claude models, and Meta's Llama models. Although these models are widely available, their terms either conflict with our release policy or leave their compatibility with it uncertain[4]. LLM-jp uses only models released under open-source licenses for training data construction, thereby minimizing uncertainty about how the resulting models and data may be used after release.

The same criterion applies to datasets released by third parties. Some publicly available datasets are distributed under permissive licenses but were constructed using external LLMs whose terms may impose restrictions on the use of the resulting data or downstream models. LLM-jp therefore examines not only the license attached to a dataset but also, to the extent possible from publicly available information, how the dataset was constructed. For this assessment, we consult papers, dataset cards, repositories, technical reports, and other public sources. If we find that a model that does not meet the LLM-jp criteria was used as part of the data construction pipeline, we do not use the dataset, even if the dataset itself is released under a permissive license.

2.3 Software Selection Criteria

LLM-jp uses software released under open-source licenses for model training and training data construction. The purpose is to allow third parties to reproduce not only the trained model but also the procedures used to build it. LLM-jp therefore selects software for every processing step whose source code can be inspected, modified, and redistributed. We also release the modifications made by LLM-jp.

2.4 Model License

We release the LLM-jp-4 models under the Apache License 2.0, a standard open-source license. LLMs have often been released under custom licenses that include their own terms of use or restrictions on particular uses (Touvron et al. 2023; Grattafiori et al. 2024). Such custom licenses can impose additional legal and administrative costs on users and may create barriers to research, development, and practical applications. In contrast, LLM-jp uses a widely adopted standard open-source license. This makes it easier for researchers, developers, companies, and other users to understand the license terms and incorporate the models into existing research and development processes.

Whether license-based use restrictions can effectively prevent model misuse remains uncertain. Users who intend to misuse a model may not comply with license restrictions. At the same time, broad or ambiguous prohibitions may require users who seek to

4 For example, OpenAI's service terms restrict the use of outputs to develop competing models, while Anthropic's commercial terms restrict using its services to develop competing products or train competing models without express approval. The Llama 3.1 and Llama 4 licenses include naming requirements for released models trained using their materials or outputs, as well as additional licensing conditions tied to a specified user threshold.

comply with the license to determine whether their intended uses are permitted, placing an additional burden and potentially discouraging research or socially beneficial applications. Use restrictions may therefore place substantial constraints on responsible use without being sufficient to prevent misuse.

The absence of use restrictions in the license does not imply that the societal impacts of model use are unimportant. We distinguish between the legal permissions granted by the license and the social and ethical responsibilities associated with the use of the models. These responsibilities include avoiding uses that infringe intellectual property rights or human rights, contribute to defamation, involve professional judgments without appropriate qualifications or expert oversight, or otherwise violate applicable laws and regulations. They also include assessing the suitability of a model for its intended purpose, considering potential risks associated with its use, and adequately verifying generated outputs before relying on them.

3. Model Architecture

We designed the model architectures to facilitate practical use and further development. A sovereign model should not only achieve high performance but also allow users to adapt and operate it according to their own goals and constraints. We therefore avoided highly specialized architectures and designs that depend strongly on specific implementations, instead favoring architectures supported by widely adopted software and toolchains.

LLM-jp-4 includes two architectures: a dense model and a Mixture-of-Experts (MoE) model. Their architectural details are summarized in Table 2. The dense model uses a standard Transformer architecture based on LLaMA 2 (Touvron et al. 2023), while the MoE model follows the general architecture of Qwen3 (Yang et al. 2025). Because the LLaMA and Qwen model families are widely adopted, they are well supported by existing open-source software and toolchains for training and inference. By following these architectures, LLM-jp-4 can benefit from this ecosystem, including software such as vLLM (Kwon et al. 2023) and Megatron-LM (Shoeybi et al. 2019), both during development and when users further train or fine-tune the released models.

Both models use Grouped Query Attention (GQA) (Ainslie et al. 2023) as the attention mechanism. GQA uses fewer key/value heads than query heads, reducing the memory required for the KV cache during inference while maintaining performance close to that of multi-head attention.

For the MoE model, we adopted a wide and shallow architecture. In preliminary experiments, we observed that the larger general matrix–matrix multiplication (GEMM) operations resulting from this design improved computational efficiency on GPUs and achieved higher training throughput.

We also adopted several MoE-specific choices for initialization and routing stability. For the MoE model, we initialized all trainable parameters from a normal distribution with a standard deviation of 0.006, following DeepSeek (Dai et al. 2024; DeepSeek-AI et al. 2024, 2025). In addition, following Radford et al. (2019), we scaled the output projection weights immediately before residual additions by the inverse square root of the total number of residual connections in the model. To improve routing stability, we applied the router z-loss during training (Zoph et al. 2022) and performed router computations in FP32. The coefficients for the load-balancing loss and router z-loss were 1×10^{-2} and 1×10^{-3}, respectively, following the settings used in OLMoE (Muennighoff et al. 2025).

Table 2: Architecture summary of LLM-jp-4 models. Heads denote Q/KV heads; experts denote total/activated experts.

Property	8B	32B-A3B
Type	Dense	MoE
Params	8.6B	32.1B
Active params	8.6B	3.8B
Layers	32	32
Hidden	4,096	2,560
MoE Hidden	–	960
Heads	32/8	40/4
QK norm	No	Yes
Experts	–	128/8
Context length	65,536	65,536

3.1 Tokenizer

LLM-jp-4 uses a new SentencePiece Unigram tokenizer (Kudo 2018; Kudo and Richardson 2018) with a vocabulary of 196,608 tokens, covering English, Japanese, Chinese, and Korean. Earlier LLM-jp tokenizers were constructed by starting from the vocabulary of an existing model and expanding it one language at a time through a multi-stage expansion-and-filtering pipeline (LLM-jp et al. 2024). In contrast, the LLM-jp-4 tokenizer was trained from scratch as a single Unigram model on a balanced multilingual mixture. This design makes cross-lingual balance an explicit and tunable property of the training data, rather than an emergent consequence of staged vocabulary expansion, and results in a markedly simpler and more reproducible construction recipe while retaining broad multilingual coverage.

The tokenizer training data was sampled from the pre-training corpus, which consists of large-scale public datasets for English, Japanese, Chinese, and Korean. Documents are sampled uniformly at the document level within each language. The sampled data were mixed in approximate proportions of 0.68 for English and code, 0.18 for Japanese, 0.09 for Chinese, and 0.05 for Korean, for a total of approximately 22 GB of text. We selected this mixture, together with the main tokenizer training hyperparameters, through a grid search over several candidate language ratios, optimizing per-language compression on held-out text as measured by both bytes per token and characters per token. The chosen mixture provided the best overall trade-off across the four languages.

A central consideration was how the tokenizer segments text before learning subword units. We retain standard whitespace pre-tokenization, ensuring that no token spans a whitespace boundary. We explicitly explored relaxing this constraint using SuperBPE-style "superword" tokens (Liu et al. 2025) that merge across whitespace. In our preliminary experiments, although such tokens improved raw compression, they degraded downstream task performance in our experiments and were therefore not adopted. We do, however, split digits into individual tokens. In our ablation experiments, this single-digit segmentation improved mathematical performance.

Text is otherwise preserved verbatim. Normalization is disabled using the identity normalizer, with no NFKC mapping; whitespace-only pieces are permitted; and repeated whitespace is preserved rather than collapsed. In addition to making tokenization faithful and reversible, preserving runs of whitespace deliberately accommodates source code in the training corpus, where indentation and alignment carry meaning. Representing

Table 3: Main training settings for the LLM-jp-4 tokenizer.

Setting	Value
Model type	Unigram (SentencePiece)
Vocabulary size	196,608
Character coverage	1.0
Byte fallback	enabled
Normalization	identity (no NFKC)
Whitespace pre-tokenization	enabled (tokens do not cross whitespace)
Digit handling	split into individual digits
Whitespace-only pieces	allowed (repeated whitespace preserved)
Maximum piece length	16
EM sub-iterations	10

such patterns with dedicated whitespace pieces, rather than normalizing them away, allows the tokenizer to handle code substantially more efficiently. Together with full character coverage and a 256-token byte-fallback set, this ensures that any UTF-8 input is representable and that no input is ever mapped to the unknown token.

The 196,608-token vocabulary consists of the 256 byte-fallback tokens; a small set of special and control tokens, namely `<unk>`, `<s>`, `</s>`, `<pad>`, `<mask>`, `<CLS>`, `<SEP>`, and an end-of-document marker `<EOD>`; 344 reserved slots, `<RESERVED_000>` through `<RESERVED_343>`, held out for control tokens that may be introduced after the tokenizer is frozen; and the remaining learned subword units. In the Hugging Face PreTrainedTokenizerFast export, the special tokens are namespaced with an `|LLM-jp>` suffix, for example `<s|LLM-jp>`, and `<EOD|LLM-jp>` is used as the end-of-sequence token. The main training settings are summarized in Table 3.

4. Pre-training

4.1 Corpus

Pre-training large language models takes a long period of time, during which new datasets are released and methods for data collection, processing, and selection continue to improve. That is, the optimal composition of a training corpus is not fixed but evolves with the availability of new data and advances in data processing techniques. In developing LLM-jp-4, we therefore improved the corpus in parallel with pre-training. We began pre-training with the corpus that we considered best at the start of training and later switched to an updated corpus that incorporated newly available data and improvements in data processing. As a result, the pre-training of LLM-jp-4 was divided into two phases, with a separate corpus used for each phase.

4.1.1 Corpus for Pre-training Phase 1

The pre-training corpus for Phase 1 was constructed with a target size of approximately 20 trillion tokens, taking the scale of the Llama 3 pre-training corpus (15 trillion tokens) (Grattafiori et al. 2024) as a reference. The corpus covers Japanese, English, Chinese, and Korean, as well as code. Because Japanese capability is a particular priority for a sovereign LLM developed in Japan, we collected Japanese data as broadly as possible, prioritizing corpus size. We also performed deduplication across the entire

Japanese corpus, as duplication in pre-training corpora is known to negatively affect model performance (Lee et al. 2022).

Table 4 lists the subcorpora included in Phase 1. All subcorpora satisfy the requirements for use in model training under the release levels defined in Section 2.1.

FineWeb Rescored. Phase 1 primarily uses existing datasets, but FineWeb-Rescored was newly constructed for LLM-jp-4. FineWeb-Rescored reproduces the construction procedure of FineWeb-Edu (Penedo et al. 2024). FineWeb-Edu is a Web corpus derived from Common Crawl by selecting documents judged to have high educational value, and its use in pre-training has been reported to substantially improve performance on STEM tasks. However, Llama-3-70B-Instruct (Grattafiori et al. 2024) was used to construct the classifier for document selection. Directly adopting FineWeb Edu could therefore introduce restrictions arising from the Llama 3 license[5], such as naming requirements for derivative models or the need for a separate agreement with Meta depending on the scale of use. We considered such restrictions inconsistent with our development policy and therefore reproduced the FineWeb-Edu construction procedure using an open-source LLM in place of Llama-3-70B-Instruct.

We followed the original FineWeb-Edu construction procedure, changing only the LLM used for annotation. First, we used Qwen3-32B (Yang et al. 2025), released under the Apache 2.0 license, to annotate the same subset of 450K FineWeb documents that had been annotated by Llama-3-70B-Instruct during the construction of FineWeb-Edu, assigning each document a label reflecting its educational value. We used the same annotation prompt as FineWeb-Edu. We then fine-tuned a pre-trained BERT-based embedding model[6] using the annotations produced by Qwen3-32B as training data.

Finally, we applied the fine-tuned classifier to all 24.5 billion documents in FineWeb to estimate the educational value of each document. This process used 128 H200 GPUs and took approximately 1.5 days.

4.1.2 Corpus Mixture Optimization for Pre-training Phase 1

To determine an appropriate corpus mixture, we varied the sampling weights of individual subcorpora in the LLM-jp Corpus v4 and examined their effects on pre-training performance. Training on a smaller amount of high-quality data may contribute more to final model performance than training on a large amount of lower-quality data. However, reducing the amount of lower-quality data also reduces the total amount of distinct information to which the model is exposed during training. Our goal was to find an appropriate balance between these two factors.

We determined the sampling weights for Phase 1 through a series of small-scale pre-training experiments, comparing downstream performance on Japanese tasks across candidate corpus mixtures. In each experiment, we fixed the model architecture to a 7.7B dense model and the training budget to 400 billion tokens.

As a baseline, we assigned the same sampling weight to every subcorpus. Under this setting, the probability of sampling from each subcorpus is proportional to its original size, resulting in a mixture consisting of 91.1% English and 3.5% Japanese data, with 97.3% of the data coming from unfiltered Web corpora. Starting from this baseline, we explored upsampling Japanese subcorpora, curated subcorpora such as Wikipedia, books, and academic papers, and Web corpora selected based on quality. Sampling weights were

chosen from $0, 1, 2, 4, 8$. Rather than performing a systematic grid search, which would have been computationally expensive, we explored promising settings heuristically based on the results of preceding experiments, resulting in 13 candidate configurations in total.

For evaluation, we used llm-jp-eval (Han et al. 2024), a benchmark covering a broad range of tasks for Japanese LLMs. We used the macro-average across the task categories

Table 5: Comparison of the MegaMath-Web-Pro-Max and MegaMath-Web-Pro-Max-OSS datasets.

Dataset	# Tokens	# Documents	Tokens / Document
MegaMath-Web-Pro-Max	79.4B	69M	∼1,140
MegaMath-Web-Pro-Max-OSS	67.4B	83M	∼810

defined by llm-jp-eval, such as natural language inference and question answering, as the primary metric.

Table 4 shows the sampling weights selected through these experiments. We assigned a weight of 8 to curated subcorpora, including Wikipedia, books, academic papers, mathematics, and code. For Web corpora, we assigned a weight of 4 to the large-scale Japanese Web corpus derived from Common Crawl. For FineWeb-Rescored, we assigned weights of 4, 1, and 0 to the high-, medium-, and low-quality subsets, respectively, based on their educational-value scores. Chinese and Korean Web corpora were assigned a weight of 1.

4.1.3 Corpus for Pre-training Phase 2

We refined the Phase 1 corpus with the goal of improving coding and mathematical capabilities. To strengthen coding performance, we expanded the code corpus by incorporating The Stack v2 (Lozhkov et al. 2024). To strengthen mathematical performance, we introduced MegaMath-Web-Pro-Max-OSS (MMWPM-OSS), our reproduction of MegaMath-Web-Pro-Max (MMWPM) (Wang et al. 2025) constructed using an open-source LLM.

MegaMath-Web-Pro-Max-OSS. MegaMath-Web-Pro-Max (MMWPM) (Wang et al. 2025) is a large-scale mathematics corpus constructed by selecting and rewriting mathematics-related documents from Common Crawl. Its construction uses Llama 3.1 70B Instruct (Grattafiori et al. 2024) for document selection and rewriting. Because models trained on outputs from Llama 3.1 may be subject to restrictions incompatible with our open-source release policy, we reconstructed the MMWPM pipeline using gpt-oss-120b (OpenAI et al. 2025) in place of Llama 3.1 70B Instruct. We refer to the resulting corpus as MegaMath-Web-Pro-Max-OSS (MMWPM-OSS). For the reconstruction, we started from all Common Crawl snapshots available through 2025.

Table 5 compares MMWPM-OSS with the original MMWPM. MMWPM-OSS contains more documents but fewer tokens in total and fewer tokens per document. Specifically, the number of documents increased from 69 million to 83 million, while the total token count decreased from 79.4 billion to 67.4 billion and the average number of tokens per document decreased from approximately 1,140 to 810. These differences may be attributable to the different models used for document selection and rewriting, as well as to implementation details that could not be reproduced from publicly available information.

4.1.4 Corpus Mixture Optimization for Pre-training Phase 2

In Phase 2, we revisited the composition of the Phase 1 pre-training corpus with the goal of improving mathematical and coding capabilities. Specifically, we considered

updating the code corpus, reducing Web data with low educational value, and adding new subcorpora, including MMWPM-OSS. Because such changes could potentially degrade general language understanding, we compared their effects through small-scale continued pre-training experiments before starting Phase 2 training.

We set the start of Phase 2 at the point where models trained approximately 6 trillion tokens. By this point, the major Japanese corpora had been consumed approximately once, making it a natural point at which to switch corpora. With a total training budget of approximately 10 trillion tokens, we planned to train on the Phase 2 corpus for an additional approximately 4 trillion tokens.

We considered the following five corpus modifications:

1. Code corpus update: replace The Stack v1 (Kocetkov et al. 2022) with The Stack v2 (Lozhkov et al. 2024).
2. English web corpus reduction: reduce the amount of FineWeb-Rescored data by decreasing the sampling multiplier for documents with scores of 2.0 or higher from 4 to 2, and that for documents with scores from 1.0 to below 2.0 from 1 to 0.
3. Mathematics corpus addition: add MMWPM-OSS, an English mathematics corpus.
4. Parallel corpus addition: add Laboro ParaCorpus, a Japanese–English parallel corpus (Zhao, Hamamoto, and Fujihara 2021).
5. Tabular document addition: add the Japanese subset of FinePDFs (Kydlíček, Penedo, and von Werra 2025).

To efficiently evaluate the effects of these corpus modifications under a limited compute budget, we constructed eight experimental configurations using a two-level Resolution III fractional factorial design with the five modifications as factors ($2^{5-2} = 8$). In a Resolution III design, main effects are aliased with two-factor interactions and therefore cannot be separated. However, because the datasets represented by the five factors differ substantially in their characteristics, we assumed that interaction effects would be relatively small and judged this design to provide an appropriate trade-off between statistical informativeness and computational cost.

For each configuration, we continued pre-training an 8B model for 100,000 steps, corresponding to approximately 210 billion tokens, starting from the Phase 1 checkpoint at 3.8 trillion tokens. We evaluated the resulting models using llm-jp-eval (Han et al. 2024) and the Swallow benchmark[7], and performed an analysis of variance on the results. We regarded a factor as showing a practically meaningful improvement when its estimated coefficient was positive, indicating an improvement from applying the modification, with $p \leq 0.05$ and Cohen's $f \geq 0.4$.

Table 6 shows the estimated effect of each factor. On the Swallow benchmark, adding MMWPM-OSS had a positive effect and was the only factor among those considered that satisfied the criteria above. On llm-jp-eval, none of the factors satisfied the criteria. In addition, the configuration incorporating all five modifications achieved the highest average score among the eight configurations. Within the scope of these experiments, we observed no clear degradation in general-task performance from strengthening the mathematics- and code-related corpora.

Although replacing The Stack v1 with The Stack v2 did not yield a clear improvement when averaged across the full benchmark suite, analysis at the subtask level showed relatively large positive contributions on MMLU and tasks related to code generation and understanding, while its contributions to general question-answering tasks such

as TriviaQA and SQuAD were smaller. The effect, therefore, varied substantially across tasks. Given the increasing emphasis on knowledge and reasoning capabilities as well as coding ability in recent LLM evaluation, we adopted this modification for Phase 2.

Based on these results, we adopted the update to The Stack v2 and the addition of MMWPM-OSS for Phase 2, while leaving the other proposed modifications unchanged. In particular, the addition of MMWPM-OSS was the only factor that satisfied our predefined criteria on the Swallow benchmark and therefore served as the primary corpus-level modification for strengthening mathematical capabilities in Phase 2.

4.2 Training

4.2.1 Training Recipe

We trained a dense 8B model and a sparse 32B-A3B mixture-of-experts (MoE) model under a common data curriculum. Within each phase, both models used the same corpus mixture, sampling weights, tokenizer, and sequence length, while their batch sizes and learning rates were configured separately.

Training comprised two consecutive phases aligned with the corpus development described above. Phase 1 used the broad-coverage mixture and ended after approximately 6.3T tokens. Phase 2 initialized from the corresponding Phase 1 checkpoint and added approximately 4.2T tokens from the revised mixture, which places greater emphasis on mathematical and code data. Each model therefore received approximately 10.5T pre-training tokens in total.

The two models processed the same number of tokens with different numbers of optimizer updates. With a sequence length of 4,096, the dense model used global batch sizes of 512 and 2,048 sequences in Phases 1 and 2, respectively, resulting in 3,000,000 updates in Phase 1 and 500,000 updates in Phase 2. The MoE model used global batch sizes of 1,024 and 2,048 in Phases 1 and 2, respectively, resulting in 1,500,000 and 500,000 updates. In both cases, the phase-wise token count is the product of the number of steps, global batch size, and sequence length: 6.3T tokens in Phase 1 and 4.2T tokens in Phase 2. Thus, differences in update counts reflect the selected batch sizes rather than differences in the amount of training data.

Table 7 summarizes the model and optimization settings. The complete training configurations are publicly available for the dense model[8], and the MoE model[9]. The

Router precision	–	float32

`--train-iters` values in the stable-run configurations are operational upper bounds; the step counts reported here are the checkpoints actually used at the phase boundaries.

4.2.2 Learning-rate Schedule

A conventional cosine schedule couples the learning-rate trajectory to a predefined stopping point. Extending such a run changes the intended schedule, while an intermediate checkpoint has already undergone partial decay. This is undesirable for a long-running training program in which the final token budget may change and checkpoints at several scales must be compared. We therefore used warmup–stable–decay (WSD) (Hu et al. 2024), which separates the main, constant-rate training trajectory from the terminal decay used to produce a completed checkpoint.

Each production run began with a 2,000-step linear warmup to the peak learning rate in Table 7, followed by a stable constant-rate segment. When a finalized checkpoint was required, we forked the stable run and decayed only the branch to zero; the main trajectory could then continue unchanged. This construction also made checkpoints at

different token budgets comparable because they shared the same warmup and stable trajectory. For both phases, we applied a one-minus-square-root decay (implemented as `minus_sqrt`) to zero. In Phase 1, the decay lasted 100,000 steps for the dense model and 50,000 steps for the MoE model. In Phase 2, it lasted 50,000 steps for both models. These settings resulted in the same number of decay tokens for both models within each phase.

Before adopting WSD for the production runs, we validated this schedule against cosine decay. A proxy-model experiment extended to 500,000 steps (approximately 2T tokens) and varied the WSD decay length and minimum learning rate. At the 100,000-step scale, a 20,000-step decay already achieved a lower final loss than cosine decay. Decay length had a substantially larger effect than choosing between the cosine minimum learning rate and zero. At 500,000 steps, long WSD decays outperformed cosine decay in both loss and aggregate Japanese and English downstream evaluations. Performance continued to improve with longer decays over the range tested. Based on these results, we adopted the one-minus-square-root decay to zero with fixed 100,000-step termination branches for dense Phase 1.

4.2.3 Hyperparameter Selection

We selected optimization settings before full-scale training using a controlled 400B-token study with an 8B dense proxy model. All runs used the same data and cosine schedule so that the effects of global batch size, AdamW β_2, attention-softmax precision, RoPE base, and document-boundary handling could be evaluated independently. The purpose of this study was not to tune each downstream task separately, but to identify changes that produced a consistent improvement across the evaluation suite.

Among the factors tested, global batch size was the only tested factor that yielded a clear and actionable gain. At a fixed token budget, reducing the batch size from 1,024 to 512, and then to 256, improved downstream performance per token and correspondingly increased the number of optimizer updates. A batch size of 256, however, did not scale efficiently to the intended GPU allocation. We therefore used 512 for dense Phase 1, balancing sample efficiency against distributed throughput. The step counts for dense Phase 2 and the MoE model were separately adjusted to preserve the common phase-wise token budgets under their respective batch sizes.

None of the other tested changes showed a robust advantage. Raising AdamW β_2 from 0.95 to 0.99 did not yield a consistent downstream improvement when combined with a batch size of 512. Reduced-precision attention softmax improved neither quality nor throughput. Resetting position IDs and attention masks at packed-document boundaries did not improve performance, while reducing the RoPE base from 500,000 to either 100,000 or 10,000 produced no consistent cross-task trend. Consequently, the production recipe retained $\beta_2 = 0.95$, float32 attention softmax, a RoPE base of 500,000, and continuous positions and attention across packed-document boundaries. Thus, among the alternatives tested for the dense Phase 1 recipe, only the reduction to a global batch size of 512 was carried forward.

4.2.4 Training System

We implemented training with Megatron-LM on the ABCI H200 GPU cluster. Model computation used bfloat16 arithmetic, while Transformer Engine provided optimized attention kernels. To reduce optimizer-state memory and communication overhead, we used Megatron-LM's distributed optimizer and overlapped gradient reduction and parameter gathering with computation. For the MoE model, grouped matrix

Figure 3: Average evaluation scores during Phase 1 and Phase 2 pre-training.

multiplications and fused token permutation were enabled to improve the efficiency of expert computation, and router logits were computed in float32 for numerical stability.

For available node allocations, we benchmarked feasible combinations of tensor, expert, pipeline, and data parallelism and used the configuration with the highest measured training throughput. This procedure changed only the mapping of a fixed training computation onto the available devices; the model, optimizer, global batch, and learning-rate settings in Table 7 remained unchanged.

4.3 Evaluation

During training, we monitored model performance using two evaluation suites: llm-jp-eval (Han et al. 2024) and the Swallow evaluation[7]. These results were used only to track training progress and should not be regarded as the final performance assessment. The final evaluation is presented in Section 7.

Figure 2 shows the evaluation scores during Phase 1 pre-training. Performance improved steadily over the course of training. For the dense 8B model, we periodically branched from the main training trajectory and applied learning-rate decay to each

branch. Specifically, we created branches whose decay schedules ended at approximately 2.1T, 4.2T, and 6.3T tokens, corresponding to decay1,2,3m in the figure. Evaluation performance improved rapidly after the onset of decay in each branch, demonstrating the benefit of terminal learning-rate decay for obtaining a finalized Phase 1 checkpoint. We selected the decay3m branch as the final Phase 1 checkpoint.

During Phase 2 pre-training, we continued to monitor evaluation performance. Figure 3 shows the evolution of performance across Phases 1 and 2. Performance improved gradually throughout Phase 2. When learning-rate decay began after approximately 10T tokens of training, however, evaluation scores increased sharply, similar to the behavior observed in Phase 1. The improvement was particularly pronounced on subtasks such as BBH_COT and GSM8K (Cobbe et al. 2021).

5. Mid-training

The goal of mid-training is to improve response quality for practical use while preserving the knowledge acquired during pre-training. To this end, we train on a mixture of the pre-training corpora and a newly curated large-scale collection of instruction-response datasets. In particular, we combine diverse instruction data covering dialogue, reasoning, mathematics, and code to improve instruction-following capabilities.

In addition, we extend the context length to improve the model's ability to handle long inputs. This extension is intended to improve performance on long-document understanding and context retention in multi-turn conversations.

5.1 Corpus

In this section, we describe the construction of LLM-jp-Corpus-Midtraining-v2, a new corpus developed for mid-training LLM-jp-4.

5.1.1 Corpus Candidates Collection

This section describes the candidate corpora collected for constructing the mid-training corpus. Table 8 lists the corpora and subsets considered as candidates. These candidates do not directly constitute the final mid-training corpus; rather, they form a candidate pool from which the data actually used for training is selected through subsequent data selection and mixture optimization.

The candidate pool builds on LLM-jp-Corpus-Midtraining-v1 (Kodama and Oda 2026), which was used for mid-training the LLM-jp-3.1 series, and was expanded primarily with datasets covering English STEM, mathematics, code, and instruction following. For Japanese, we included LLM-jp-Corpus-Midtraining-v1 as a candidate and additionally collected Japanese subsets from multilingual datasets.

When collecting candidate corpora, we required that they be released under licenses satisfying the requirements of OSAID and that they could be used in a manner consistent with Japanese copyright law. See Section 2.1 for details of the data selection criteria.

5.1.2 Regeneration of LLM-jp-Corpus-Midtraining-v1

LLM-jp-Corpus-Midtraining-v1 is a corpus that integrates existing instruction-response datasets, but some of its synthetic examples varied in quality with respect to question clarity and answer completeness. We therefore regenerated the synthetic data in LLM-jp-Corpus-Midtraining-v1 using gpt-oss-120b (OpenAI et al. 2025), rewriting both the questions and answers into a form better suited for mid-training.

Table 8: Candidate corpora for mid-training. A hyphen (–) in the candidate subsets column indicates that all subsets were included as candidates.

LLM-jp-Corpus-Midtraining-v1 consists of Japanese and English instruction–response data organized into four categories: general, math, coding, and reasoning. For each input sample, we applied a prompt template corresponding to its category and language. The templates instructed the model to rewrite the original question as a natural, unambiguous, and self-contained instruction while regenerating the answer as an accurate and complete response. For mathematics data, the model was instructed to include intermediate calculations and solution steps; for coding data, to provide

executable code together with an explanation; and for reasoning data, to include the reasoning process necessary to solve the problem. The prompt templates are provided in Appendix 2.

5.1.3 Corpus Mixture Optimization for Mid-training

For mid-training corpus selection, we used a two-level Resolution IV fractional factorial design with eight candidate corpora as factors, resulting in 16 experimental configurations. The eight factors were as follows.

A. Cosmopedia v2: add the cosmopedia-v2 subset of SmolLM-Corpus (allal et al. 2025).
B. Nemotron Post-Training Dataset v1: add the STEM subset.
C. Swallow Code v2: add the swallowcode-v2 subset.
D. Synthetic Code Review: add the Synthetic-Code-Review subset of Nemotron Pretraining Code v2.
E. Synthetic Question Answering: add the Synthetic-Question-Answering subset of Nemotron Pretraining Code v2.
F. Synthetic Rewriting: add the Synthetic-Rewriting subset of Nemotron Pretraining Code v2.
G. Synthetic Student Teacher: add the Synthetic-Student-Teacher subset of Nemotron Pretraining Code v2.
H. Synthetic Transpilation: add the Synthetic-Transpilation subset of Nemotron Pretraining Code v2.

The baseline corpus consisted of the regenerated LLM-jp-Corpus-Midtraining-v1, FLAN (Longpre et al. 2023) and DolminoSynthMath from DOLMino Mix 1124 (Walsh et al. 2025), Stack Exchange, and GSM8K (Cobbe et al. 2021), with a sampling weight of 8 assigned to each subset. The sampling weights of factors A–H were set to 4, 1, 2, 1, 0.5, 1, 4, and 4, respectively, such that including all eight corpora would yield approximately a 1:1 token ratio between the added corpora and the baseline corpus.

For each configuration, we continued training the dense 8B model for 12,000 steps, starting from the pre-training Phase 2 checkpoint at step 250,000, which was obtained by

applying learning-rate decay from step 200,000 to 250,000. We used a global batch size of 2,048 and a peak learning rate of 3×10^{-4}, with 2,000 warmup steps, 4,000 constant-rate steps, and 6,000 one-minus-square-root decay steps. To evaluate the resulting models, we used llm-jp-eval (Han et al. 2024), the Swallow benchmark[7], and MT-Bench (EN/JA) (Zheng et al. 2023). We additionally applied the same SFT procedure used for LLM-jp-3 to each model and evaluated the SFT models on these benchmarks as well as JHumanEval and HumanEval. We then performed analysis of variance (ANOVA) and reported signed Cohen's f, with the sign determined by the estimated main effect.

Table 9 shows the estimated effect sizes. The STEM data from Nemotron Post-Training Dataset v1 showed positive effects on multiple benchmarks, particularly before SFT. The code-related corpora generally improved JHumanEval and HumanEval after SFT, although their effects on general-purpose benchmarks such as llm-jp-eval and the Swallow benchmark varied across datasets. In particular, Synthetic-Code-Review showed a large positive effect on HumanEval, while Synthetic-Student-Teacher showed positive effects on MT-Bench. In contrast, Synthetic-Transpilation showed negative effects on MT-Bench, JHumanEval, and HumanEval after SFT, with no clear advantage over the other code-related corpora.

Based on these results and our emphasis on reasoning and coding capabilities, we selected the seven candidate corpora other than Synthetic-Transpilation for mid-training. In addition to these corpora, we included the LLMC Math Dataset, a Japanese mathematics dataset newly developed in this work for post-training. As improving mathematical capabilities was also a key objective of mid-training, we also incorporated this dataset into the mid-training corpus. Details of its construction and filtering are provided in Section 6.2.1.

The final composition and sampling weights of LLM-jp-Corpus-Midtraining-v2 are shown in Table 10.

We also conducted a small grid search over the learning rate and data mixture used for mid-training. We compared learning-rate multipliers of $\{1, 1/2, 1/3\}$ relative to the pre-training learning rate and mid-training data ratios of $\{0.5, 0.6, 0.8\}$. The results showed different trends for Japanese and English evaluation. For Japanese, settings with a higher learning rate and a larger proportion of mid-training data performed better, whereas for English, halving the learning rate and using 50% mid-training data yielded better results. Because the improvement on the English evaluation was larger, we ultimately set the learning rate to $1/2$ of the pre-training value and used a 5:5 mixture of mid-training data and Phase 2 pre-training data.

5.2 Training Setup

Mid-training continued the dense 8B model and the sparse 32B-A3B mixture-of-experts (MoE) model from their respective final pre-training Phase 2 checkpoints. The model architectures, tokenizer, and RoPE base were unchanged from pre-training. Both models used a common data curriculum throughout mid-training: the sampler assigned a total weight of 0.5 each to the pre-training mixture and the mid-training corpus described above.

Mid-training comprised two phases: Phase 1 used a sequence length of 4,096 tokens (Stage 1), while Phase 2 extended it to 16,384 and then 65,536 tokens (Stages 2 and 3). The global batch size decreased from 2,048 to 512 and then to 128 sequences, leaving the number of tokens per optimizer update fixed at 8,388,608 across all three stages. The first stage ran for 100,000 updates, and the second and third stages each ran for 25,000 updates. These settings correspond to approximately 0.84T, 0.21T, and 0.21T tokens,

Table 10: Corpora included in the final mid-training corpus and their sampling weights. Token counts denote the size of each source before sampling. When multiple subsets are listed in one row, the reported sampling weight applies to each subset unless otherwise indicated. A dagger (†) indicates a corpus that is also included in the Phase 2 pre-training corpus.

Training tokens	0.84T	0.21T	0.21T
Dense learning rate	1.5×10^{-4}	1.5×10^{-4}	$1.5 \times 10^{-4} \rightarrow 0$
MoE learning rate	2.0×10^{-4}	2.0×10^{-4}	$2.0 \times 10^{-4} \rightarrow 0$

respectively, or 1.26T mid-training tokens per model in total. Table 11 summarizes this trajectory.

Stage 1 used a 2,000-step linear warmup followed by a stable constant-rate segment, and Stage 2 continued at the same model-specific learning rate without an additional warmup. Stage 3 formed the terminal decay segment of the WSD schedule, applying a one-minus-square-root decay to zero over its 25,000 updates. Both models used AdamW with $(\beta_1, \beta_2) = (0.9, 0.95)$, $\epsilon = 10^{-8}$, weight decay of 0.1, and gradient clipping at 1.0. The remaining numerical settings were inherited from pre-training, including bfloat16 model computation and float32 attention softmax.

Training otherwise followed the system setup used for pre-training, with context parallelism additionally enabled for Stages 2 and 3.

5.3 Evaluation

As in the pre-training evaluation (Section 4.3), we monitored downstream performance throughout mid-training. Figure 4 shows the performance trajectories for selected subtasks from llm-jp-eval and the Swallow evaluation, together with the overall average score, across pre-training and mid-training.

Overall, mid-training, which is intended to improve instruction following and extend the context length, largely preserved short-context performance across many tasks. Some tasks improved substantially immediately after the start of mid-training. In particular, NLI, BBH_COT, GSM8K, and SQuAD2 showed rapid gains during the initial ramp-up period. Other tasks improved later in training, with MR and MMLU contributing notably to the overall performance gain.

However, some tasks showed performance degradation during mid-training, including GSM8K, XWinograd_en, and OpenBookQA. In particular, although GSM8K performance improved sharply at the beginning of mid-training, it subsequently declined. This degradation was temporary, as performance recovered during post-training. This pattern may reflect temporary specialization to the mid-training distribution rather than a loss of the underlying mathematical capability.

6. Post-training

During post-training, we aim to improve the instruction-following capabilities of the mid-trained checkpoint as a conversational model. The post-trained LLM-jp-4 model is designed as a thinking model that first performs reasoning and then generates a final answer. We do not use reinforcement learning in post-training; instead, the model is

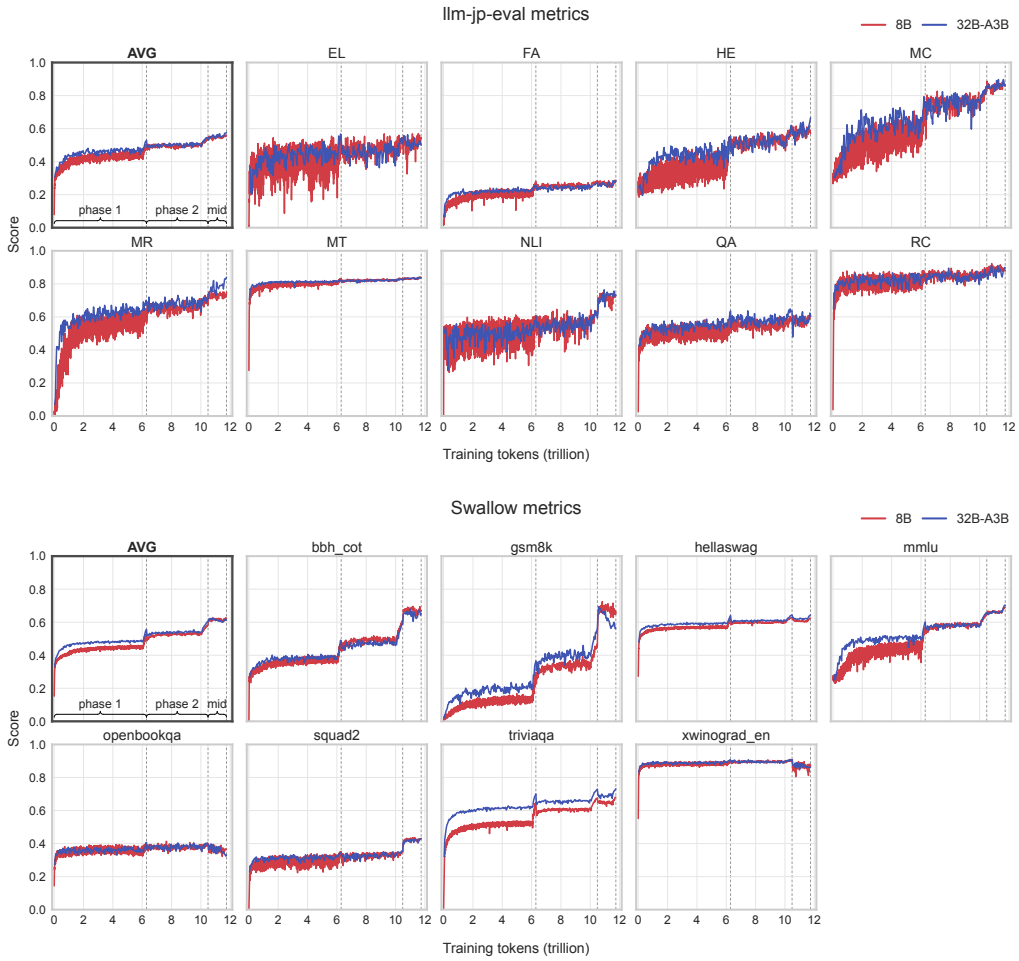

Figure 4: Evolution of the average score (AVG) and selected subtask scores from llm-jp-eval and the Swallow evaluation across pre-training Phases 1 and 2 and mid-training.

aligned in two stages using supervised fine-tuning (SFT) followed by direct preference optimization (DPO).

6.1 Chat Template

For the LLM-jp-4 thinking models, we adopt the OpenAI Harmony response format as the chat template (OpenAI et al. 2025). In addition to roles such as `system`, `user`, and `assistant`, this format assigns a channel to each assistant message, allowing the model to distinguish between the `analysis` channel, which represents the internal reasoning process, and the `final` channel, which contains the final answer presented to the user.

For LLM-jp-4, we adapt the construction of the system message while otherwise retaining the Harmony response format[10]. First, we replace the default model identity, which identifies the model as OpenAI's ChatGPT, with a statement identifying it as LLM-jp-4, trained by LLM-jp. Second, rather than using a fixed knowledge cutoff, the system message uses the value of `knowledge_cutoff` when provided and defaults to `2025-12` otherwise. Third, for the current date, it similarly uses `conversation_start_date` when provided and otherwise uses the date at runtime. Other aspects of the format, including reasoning effort, the `analysis`, `commentary`, and `final` channels, the rendering of tool definitions, the handling of developer messages, and the separation of `thinking` and `content` in assistant messages, are retained without modification.

Below, we show an example of applying the chat template. When `add_generation_prompt=True` is used at inference time, only the start token of the assistant message is appended after the system and user messages, and the model generates the subsequent tokens. In this example, we set `reasoning_effort=medium` and `conversation_start_date=2026-06-17`.

Serialized chat template for inference

```
<|start|>system<|message|>You are LLM-jp-4, a large language model trained by
LLM-jp.
Knowledge cutoff: 2025-12
Current date: 2026-06-17

Reasoning: medium

# Valid channels: analysis, commentary, final.
Channel must be included for every message.<|end|>
<|start|>user<|message|>What is the capital of Japan?<|end|><|start|>assistant
```

For SFT and DPO training data, the `thinking` field of each assistant message is serialized as the `analysis` channel, while the `content` field is serialized as the `final` channel. For the final assistant turn, `<|return|>` is appended to the end of the `final` channel so that the model learns to indicate the end of the assistant turn.

Serialized chat template for training

```
<|start|>system<|message|>You are LLM-jp-4, a large language model trained by
LLM-jp.
Knowledge cutoff: 2025-12
Current date: 2026-06-17

Reasoning: medium

# Valid channels: analysis, commentary, final.
Channel must be included for every message.<|end|>
<|start|>user<|message|>What is the capital of Japan?<|end|>
<|start|>assistant<|channel|>analysis<|message|>
The question asks for the capital city of Japan.<|end|>
<|start|>assistant<|channel|>final<|message|>The capital of Japan is
Tokyo.<|return|>
```

6.2 Supervised Fine-tuning (SFT)

For SFT, we collect prompts from multiple instruction data sources and construct a dataset by augmenting each prompt with a reasoning process and a final answer. For portions of the resulting SFT dataset whose licenses permit redistribution, we release the data as `llm-jp-4-thinking-sft-data`[11].

6.2.1 Data Sources

The SFT data were collected from multiple data sources covering a broad range of tasks, including dialogue, instruction following, mathematics, coding, reasoning, and knowledge extraction. We collected data in both English and Japanese. Table 12 lists the data sources used for SFT. As with the pre-training and mid-training corpora, each data source was selected according to the data selection criteria described in Section 2.1.

Nemotron-IF-Chat-v1 (Chat) consists of instances from the Nemotron-IF-Chat-v1 dataset whose `capability_target` is `chat`. Nemotron-IF-Chat-v1 (IF) consists of instances whose `capability_target` is `if`, together with the `structured_outputs` subset.

Ichikara-instruction is a manually created Japanese instruction–response dataset. We use it for training LLM-jp-4 under a license agreement that permits us to release models trained on the data, including for commercial use. In this work, we use three subsets: ichikara-instruction (ver004-002), ichikara2 (ver002-001), and ichikara-multiturn (ver002-002). In addition, we use the manually created seed examples prepared for generating Japanese Synthetic Instruction Following, a synthetic instruction-following dataset inspired by the ichikara dataset.

11 `https://huggingface.co/datasets/llm-jp/llm-jp-4-thinking-sft-data`

LLMC Math Dataset is a newly developed Japanese mathematics dataset consisting of problem statements, reasoning traces, and final answers, all written in Japanese using TEX notation. The dataset is designed to align with the content specified in the latest curriculum guidelines issued by the Ministry of Education, Culture, Sports, Science and Technology (MEXT) for junior and senior high schools in Japan. It covers problems ranging from basic exercises to relatively easy entrance-examination-level questions across a broad range of topics, including positive and negative numbers, expansion and factorization, linear equations, systems of linear equations, inequalities, square roots, quadratic equations, elementary number theory, permutations and combinations, sequences, probability and statistics, trigonometric functions, exponential and logarithmic functions, differentiation and integration, limits, vectors, and complex numbers. Geometry problems that require interpreting figures are excluded from the dataset.

For this study, we manually constructed 2,243 problems. In addition to these human-authored examples, we augmented the dataset using gpt-oss-120b (OpenAI et al. 2025) by generating analogous problems from each original problem. To promote diversity, generation was performed under a variety of conditions. Specifically, we used a relatively high temperature (`temperature = 0.9`) and introduced additional randomness through prompts such as "create a problem using the following numerical values if necessary," or providing hints for problem modification, such as "change the names of people appearing in the problem statements." In this way, we attempted to generate an analogous problem from each original problem 100 times under varying conditions. After removing failed generations and further filtering the generated data using LLM-as-a-Judge to exclude examples with mathematically incorrect reasoning or answers, we ultimately obtained and used approximately 150,000 problems.

System Prompt Questions was created to guide the model to correctly answer questions about its identity based on what is written in its system prompt. We consider four variables: knowledge cutoff date, current date, model name, and organization name. This dataset targets users who might want to modify these fields and expect the model to follow what is written in the system prompt. We first created 20 questions for each category, comprising 10 English and 10 Japanese questions, for a total of 80 base prompts. We then used gpt-oss-120b (OpenAI et al. 2025) to generate responses to each prompt at three reasoning effort levels (low, medium, and high), yielding 240 examples in total. To increase variation in the system-prompt information, we subsequently replaced the values of the four variables using a rule-based procedure. Dates were sampled randomly, while model and organization names were replaced with randomly selected fictitious names generated by gpt-oss-120b.

Self-System Questions was designed to train the model to answer questions in three categories: (1) the LLM-jp organization and its models; (2) the model development process, including corpus construction, training, and evaluation; and (3) safety-related topics. The questions were manually written by professional annotators, while the corresponding answers were collected from volunteers within LLM-jp. From these data, we manually selected and slightly revised 125 Japanese question–answer pairs. We then translated them into English; one question was omitted because it was highly dependent on Japanese-specific context, resulting in 124 English question–answer pairs. The final dataset therefore contains 249 pairs: 125 in Japanese and 124 in English. Finally, we provided the questions and answers to gpt-oss-120b and used it to generate corresponding reasoning traces.

Table 13: Input prompts, synthetic targets, and number of SFT samples after filtering. R_1 and A_1 denote the generated reasoning process and final answer for the first assistant turn, respectively. R_2 and A_2 denote those for the additional second assistant turn. Filtered samples are reported for low/medium/high reasoning effort.

6.2.2 Reasoning Data Generation

To adapt the SFT data to the response format of the LLM-jp-4 thinking models, we used gpt-oss-120b (OpenAI et al. 2025) to synthesize reasoning processes and final answers. During generation, we used three reasoning effort levels—low, medium, and high—and constructed separate training data for each level. Table 13 summarizes, for each data source, the number of input prompts, the components synthesized, and the number of samples retained after filtering.

The components to be synthesized were determined according to the nature of the original responses and the conversational structure of each data source. For most data sources, we generated a new reasoning process R_1 and final answer A_1 for the first assistant turn. For data sources used to train multi-turn responses, we additionally synthesized a second user turn following the first assistant response and generated a reasoning process R_2 and final answer A_2 in response to it. This procedure allowed us to construct multi-turn data that require the model to respond while carrying over the preceding context, in addition to single-turn instruction-following data. For AnswerCarefully, which contains safety-related instructions, we prioritized preserving the original answers and therefore synthesized only the reasoning process R_1, leaving the original final answer A_1 unchanged.

We applied three stages of filtering to the generated data. First, we removed samples that did not conform to the OpenAI Harmony response format. Specifically, samples in which the assistant's reasoning process and final answer were not properly separated into the prescribed format were mechanically filtered out.

Second, we removed samples containing questions about the model itself. Because questions concerning the model identity and system configuration are handled separately in Self-System Questions and System Prompt Questions, we considered other self-

referential questions unsuitable for inclusion in the training data. We performed this classification using gpt-oss-120b as an LLM-as-a-Judge.

Third, we filtered samples based on the quality of the reasoning process and final answer. Using gpt-oss-120b as an LLM-as-a-Judge, we rated each response on a five-point scale along five dimensions: Accuracy, Fluency, Detail, Relevance, and Overall quality. Only samples receiving the maximum score of 5 on all five dimensions were retained for training. For multi-turn data, responses at each turn were evaluated separately; when the second-turn response failed to meet the filtering criteria, we retained the conversation only up to the first turn.

6.2.3 Training Setup

SFT was performed using the mid-trained dense 8B and MoE 32B-A3B models as the initial checkpoints. To efficiently train the models with a 64K context length, we employed fixed-length packing. Specifically, after tokenization, all samples within each dataset were concatenated and split into fixed-length chunks of 64K tokens. This approach improves training efficiency by packing multiple short samples into a single sequence rather than padding each sample individually. Any trailing tokens that did not form a complete 64K-token chunk were discarded, such that only full-length chunks were used for training.

As is common in SFT, the system and user messages were excluded from the loss computation, and the loss was computed only over the assistant's reasoning process and final answer.

We used AdamW (Loshchilov and Hutter 2019) for optimization, with a global batch size of 64, a weight decay of 0.1, $\beta_1 = 0.9$, and $\beta_2 = 0.98$. For the learning rate schedule, we used the Warmup-Stable-Decay (WSD) schedule (Hu et al. 2024). Specifically, the learning rate was linearly warmed up to 4.0×10^{-5} over the first 5% of the training steps, held constant at this peak learning rate for the next 20%, and then decayed to 0.0 over the remaining steps using 1-sqrt annealing (Hägele et al. 2024).

Table 14 reports the number of tokenized chunks, training chunks, upsampling factor, and training tokens per epoch for each subset. We upsampled several small but important data sources, using upsampling factors of 16, 8, and 5 for AnswerCarefully, System Prompt Questions, and Self-System Questions, respectively. For Self-System Questions and System Prompt Questions, the data were first duplicated twice to construct complete 64K-token chunks, which would otherwise have been discarded. After upsampling, the final SFT mixture consists of 82,615 chunks, corresponding to approximately 5.41B tokens per epoch. We trained for two epochs, resulting in approximately 10.83B training tokens in total.

6.3 Direct Preference Optimization (DPO)

Following SFT, we perform preference alignment using Direct Preference Optimization (DPO) (Rafailov et al. 2023). DPO is trained on pairs of preferred and non-preferred responses to the same prompt, increasing the relative likelihood of the preferred response while regularizing the model against excessive deviation from a reference model. For LLM-jp-4, we construct separate DPO datasets for the 8B and

Table 14: Number of tokenized chunks, training chunks, upsampling factors, and training tokens for each SFT source. The number of training tokens is computed as the number of training chunks multiplied by 64K tokens.

32B-A3B models and release them as `llm-jp-4-8b-thinking-dpo-data`[12] and `llm-jp-4-32b-a3b-thinking-dpo-data`[13], respectively.

12 https://huggingface.co/datasets/llm-jp/llm-jp-4-8b-thinking-dpo-data

6.3.1 Preference Data Construction

We constructed the preference data for DPO by generating multiple candidate responses from each SFT model, scoring them with a judge model, and selecting response pairs with large differences in their scores. The input prompts were primarily sampled at random from the SFT datasets. The only additional data source introduced specifically for DPO was AnswerCarefully Self-Instruct[14], which focuses on safety-related instructions. For each prompt, we sampled four responses from the corresponding SFT model using a temperature of 1.0 and top-p of 0.95. We used `gpt-oss-120b` as the judge model to score the generated responses.

We used two types of evaluation prompts: a general helpfulness judge prompt and a safety judge prompt. For most data sources, we used the helpfulness judge prompt, which assigns an integer helpfulness score from 1 to 10 based on the usefulness, relevance, correctness, depth, creativity, and specificity of the response. For AnswerCarefully Self-Instruct, we instead used the safety judge prompt for safety alignment, assigning an integer safety score from 1 to 5. Both judge prompts explicitly instructed the judge not to penalize differences in reasoning length arising from different reasoning effort levels, and to base the evaluation primarily on the helpfulness or safety of the final answer. The helpfulness and safety judge prompts used in our experiments are shown in Appendix 3.

To construct preference pairs, we selected the highest-scoring candidate response to each prompt as the chosen response and the lowest-scoring candidate as the rejected response. When multiple responses shared the same score, we selected one chosen response from among the highest-scoring responses and up to two rejected responses from among the lowest-scoring responses using a fixed random seed.

For helpfulness data, we retained only examples for which the highest score was greater than 6 and the difference between the highest and lowest scores was at least 2. For safety data, we required the highest score to be greater than 3 and the score difference to be at least 1. In addition, to mitigate length bias arising from differences in final-answer length between the chosen and rejected responses, we excluded pairs for which the ratio of their token lengths exceeded 1.5.

6.3.2 Training Setup

DPO was performed using the SFT-trained dense 8B and MoE 32B-A3B models as the initial checkpoints. We used the corresponding SFT model at the start of training as the reference model and set the KL regularization coefficient in the DPO objective to $\beta = 0.5$. The log probabilities of the chosen and rejected responses were not normalized by sequence length; instead, the preference loss was computed using the sum of token log probabilities over the entire response.

To accommodate the 64K context length, we retained only preference pairs for which both the chosen and rejected sequences were at most 64K tokens after tokenization. Samples exceeding 64K tokens were excluded from training, and all retained sequences were padded to 64K tokens.

We used AdamW (Loshchilov and Hutter 2019) for optimization, with a weight decay of 0.1, $\beta_1 = 0.9$, and $\beta_2 = 0.98$. The global batch size was 256, with a micro batch size of 1. As in SFT, we used the Warmup-Stable-Decay (WSD) learning rate schedule (Hu et al. 2024). Specifically, the learning rate was linearly warmed up to 9.0×10^{-7} over the

first 5% of the training steps, held constant at this peak learning rate for the next 20%, and then decayed to 0.0 over the remaining steps using 1-sqrt annealing (Hägele et al. 2024). We trained for two epochs. Table 15 reports the number of training preference pairs for each subset.

7. Evaluation

We evaluate the English and Japanese capabilities of LLM-jp-4 from two perspectives: automatically scored benchmarks with ground-truth answers and conversational evaluation using LLM-as-a-Judge. For the automatically scored benchmarks, we compare LLM-jp-4 with llm-jp-3.1-8x13b-instruct4, the flagship model of the previous-generation LLM-jp-3 series, as well as Qwen3-8B (Yang et al. 2025) and gpt-oss-20b (OpenAI et al. 2025), open-weight models developed by other organizations with relatively similar parameter scales. For the LLM-as-a-Judge evaluation, we compare LLM-jp-4 with gpt-oss-20b (OpenAI et al. 2025) and additionally include GPT-4o and GPT-5.4 as reference models.

7.1 Evaluation Benchmarks

For automatically scored benchmarks with ground-truth answers, we use llm-jp-eval v2.1.3 (Han et al. 2024). Llm-jp-eval groups individual benchmark tasks into categories such as natural language inference and question answering. We report the average score for each category separately for the Japanese and English subsets. In addition, we analyze several challenging benchmarks individually, including MMLU (Hendrycks et al. 2021), JMMLU (Yin et al. 2024), GPQA (Rein et al. 2024), AIME[15], HLE (Center for AI Safety, Scale AI, and HLE Contributors Consortium 2026), and BBH (Suzgun et al. 2022), rather than aggregating them only into category-level averages.

To evaluate response quality as conversational models, we additionally conduct LLM-as-a-Judge evaluation using llm-jp-judge[16]. Llm-jp-judge is a framework for unified LLM-as-a-Judge evaluation in Japanese and English. In this work, we use MT-Bench (EN/JA) (Zheng et al. 2023), AnswerCarefully (Suzuki et al. 2026), and llm-jp-instructions. MT-Bench (Zheng et al. 2023) evaluates multi-turn conversational problem-solving capabilities, and we use both the original English version and its Japanese translation[17]. AnswerCarefully (Suzuki et al. 2026) evaluates safety and cautious response behavior in Japanese; we use 336 questions from its v2.0 test set. Llm-jp-instructions is a manually created single-turn Japanese question-answering dataset, from which we use 400 questions from the test set. For all LLM-as-a-Judge evaluations, we use `gpt-5.4-2026-03-05` as the judge model and report the average score over three independent inference and evaluation runs. For datasets used in both post-training and evaluation, we used only their training splits for post-training and their test splits for evaluation.

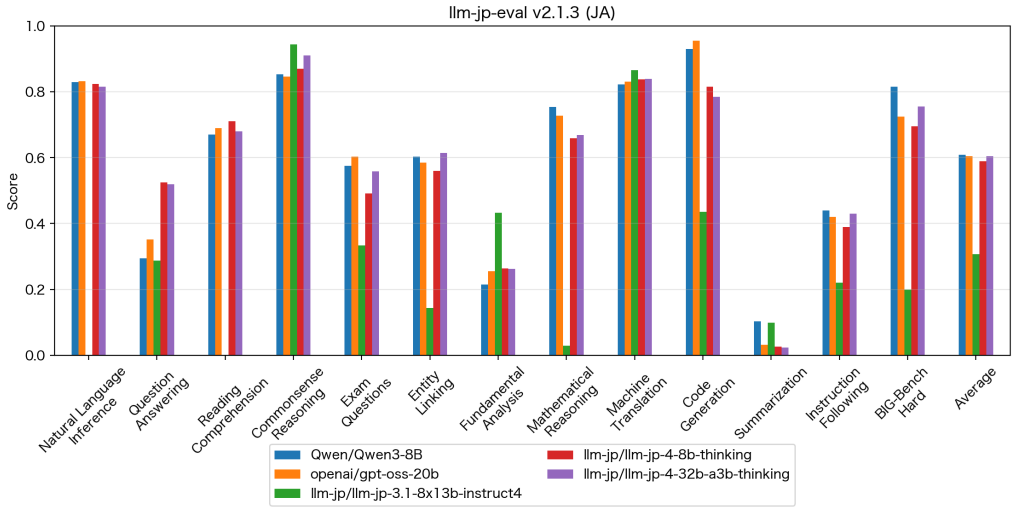

Figure 5: Scores by task category on the Japanese subset of llm-jp-eval v2.1.3.

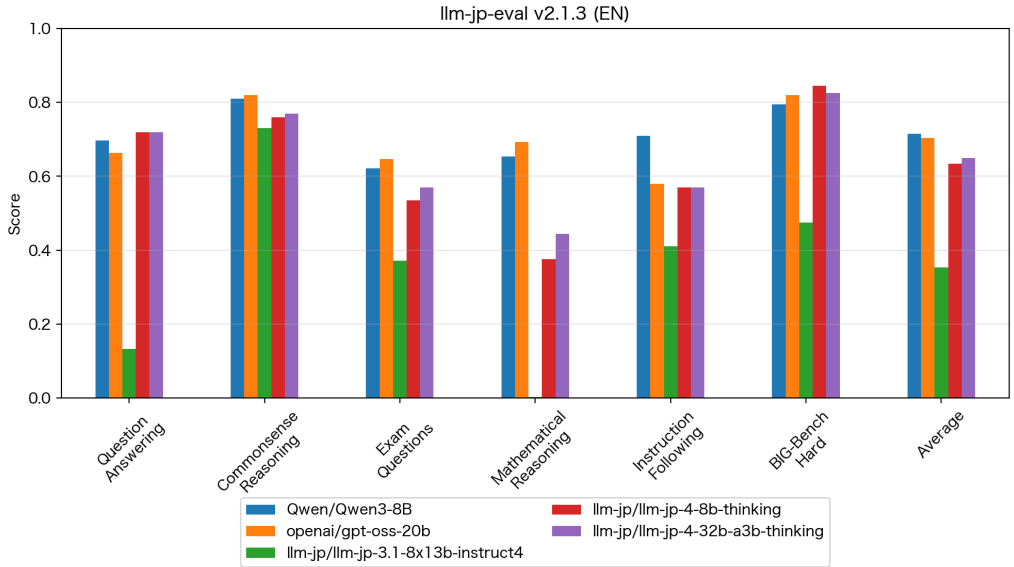

Figure 6: Scores by task category on the English subset of llm-jp-eval v2.1.3.

7.2 Evaluation with llm-jp-eval v2.1.3

Figure 5 shows the scores by task on the Japanese subset of llm-jp-eval v2.1.3. LLM-jp-4 substantially improves upon llm-jp-3.1-8x13b-instruct4, the flagship model of the

15 https://maa.org/maa-invitational-competitions/
16 https://github.com/llm-jp/llm-jp-judge
17 https://github.com/Stability-AI/FastChat

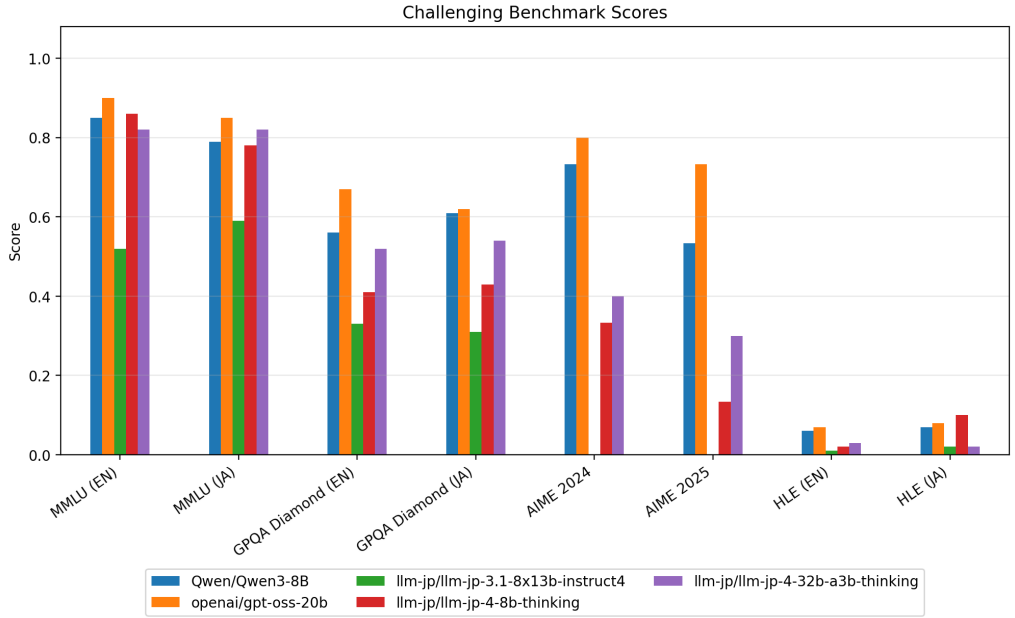

Figure 7: Scores on challenging benchmarks requiring knowledge and reasoning.

previous generation. The average Japanese score increases from 0.307 for llm-jp-3.1-8x13b-instruct4 to 0.590 for the 8B dense model and 0.605 for the 32B-A3B MoE models. In particular, the 32B-A3B model achieves Japanese performance comparable to Qwen3-8B (0.608) and gpt-oss-20b (0.604).

Figure 6 shows the scores by task on the English subset of llm-jp-eval v2.1.3. LLM-jp-4 also shows substantial improvements over the previous-generation model on the English subset. The average English score increases from 0.354 for llm-jp-3.1-8x13b-instruct4 to 0.634 for the 8B dense model and 0.650 for the 32B-A3B MoE model. Although these scores remain below those of Qwen3-8B (0.714) and gpt-oss-20b (0.704), they represent substantial improvements over the previous generation.

Figure 7 shows the results on challenging benchmarks requiring knowledge and reasoning. The improvements over the previous generation are particularly pronounced on these tasks. On JMMLU, llm-jp-4-32b-a3b-thinking achieves a score of 0.820, compared with 0.590 for llm-jp-3.1-8x13b-instruct4. On Japanese GPQA Diamond, the score likewise improves from 0.310 for llm-jp-3.1-8x13b-instruct4 to 0.540 for llm-jp-4-32b-a3b-thinking.

However, gaps remain relative to the external baselines on challenging science and mathematics tasks. On GPQA Diamond (EN), llm-jp-4-32b-a3b-thinking scores 0.520, below Qwen3-8B (0.560) and gpt-oss-20b (0.670). On AIME 2024/2025, llm-jp-4-32b-a3b-thinking achieves scores of 0.400/0.300; although this represents a substantial improvement over the previous generation, it still falls short of Qwen3-8B and gpt-oss-20b. Scores on HLE are low across all models, and the results indicate substantial room for further improvement in LLM-jp-4.

Table 16: LLM-as-a-Judge conversational evaluation results. Scores are averaged over three inference and evaluation runs. MT-Bench scores range from 1 to 10, while AnswerCarefully and llm-jp-instructions scores range from 1 to 5, with higher scores indicating better performance. Low, medium, and high indicate the reasoning effort setting used during inference.

Model	MT-Bench JA	MT-Bench EN	AnswerCarefully	llm-jp-inst.
gpt-4o-2024-08-06	7.29	7.69	4.00	4.07
gpt-5.4-2026-03-05 (low)	8.87	8.76	4.38	4.79
gpt-5.4-2026-03-05 (medium)	8.87	8.89	4.43	4.82
gpt-5.4-2026-03-05 (high)	8.98	8.85	4.41	4.83
gpt-oss-20b (low)	7.21	7.95	3.39	3.08
gpt-oss-20b (medium)	7.33	7.85	3.55	3.16
llm-jp-4-8b-thinking (low)	7.23	7.54	3.58	3.50
llm-jp-4-8b-thinking (medium)	7.54	7.79	3.69	3.54
llm-jp-4-32b-a3b-thinking (low)	7.57	7.70	3.61	3.61
llm-jp-4-32b-a3b-thinking (medium)	7.82	7.86	3.70	3.61

7.3 Evaluation with LLM-as-a-Judge

Table 16 presents the LLM-as-a-Judge evaluation results on MT-Bench, AnswerCarefully, and llm-jp-instructions. With reasoning effort set to medium, llm-jp-4-8b-thinking achieves scores of 7.54 on MT-Bench (JA), 7.79 on MT-Bench (EN), 3.69 on AnswerCarefully, and 3.54 on llm-jp-instructions. With low reasoning effort, the corresponding scores are 7.23, 7.54, 3.58, and 3.50, respectively, indicating that the medium setting yields particularly clear improvements on MT-Bench and AnswerCarefully.

With medium reasoning effort, llm-jp-4-32b-a3b-thinking achieves scores of 7.82 on MT-Bench (JA), 7.86 on MT-Bench (EN), 3.70 on AnswerCarefully, and 3.61 on llm-jp-instructions, achieving higher average scores than the 8B model on all four benchmarks. For comparison, gpt-oss-20b with medium reasoning effort scores 7.33 on MT-Bench (JA), 7.85 on MT-Bench (EN), 3.55 on AnswerCarefully, and 3.16 on llm-jp-instructions. Thus, llm-jp-4-32b-a3b-thinking outperforms gpt-oss-20b on Japanese MT-Bench, AnswerCarefully, and llm-jp-instructions, while achieving comparable performance on English MT-Bench.

8. Conclusion

We introduced LLM-jp-4, a family of sovereign language models developed with an emphasis on transparency, reproducibility, and practical usability. Throughout development, we adopted explicit criteria for selecting datasets, external models, and software so that the resulting models and their development process support independent inspection and reproduction. We also described the empirical studies that informed major design decisions, including corpus composition, optimization settings, mid-training data selection, and post-training. The resulting models substantially improve upon the previous LLM-jp generation and achieve competitive performance against strong open-weight baselines. Our experience with LLM-jp-4 suggests that requirements for transparency, reproducibility, and licensing compliance need not preclude competitive model performance. We hope that the development principles, training recipes, data construction procedures, and experimental findings reported in this work provide a

useful reference for future development of transparent and reproducible sovereign language models.

1. Contribution Statement

LLM-jp-4 was a collaborative effort involving contributions from multiple working groups. We list the authors' main contributing roles below, while recognizing that many contributions spanned multiple aspects of the project. Authors are listed alphabetically by first name within each category.

- **For infrastructure setup:** Taishi Nakamura, Takashi Kodama, Yusuke Oda.
- **For model architecture:** Chaoran Liu, Jun Suzuki, Rio Yokota, Taishi Nakamura, Takashi Kodama, Yusuke Oda.
- **For pre-training methodology:** Rio Yokota, Taishi Nakamura, Takashi Kodama, Yusuke Oda.
- **For pre-training data curation:** Chaoran Liu, Daisuke Kawahara, Hirokazu Kiyomaru, Takashi Kodama, Yun-Ang Wu, Yusuke Oda.
- **For mid-training methodology:** Takashi Kodama, Yusuke Oda.
- **For mid-training data curation:** Daisuke Kawahara, Hirokazu Kiyomaru, Koshi Eguchi, Sosuke Hosokawa, Takashi Kodama, Yusuke Oda.
- **For post-training methodology:** Takashi Kodama.
- **For post-training data curation:** Hideyuki Tachibana, Takashi Kodama, Yun-Ang Wu, Yusuke Oda.
- **For evaluation methodology:** Takashi Kodama, Yusuke Miyao.
- **For model evaluation:** Hideyuki Tachibana, Hirokazu Kiyomaru, Kouta Nakayama, Qianying Liu, Ryo Takahashi, Takashi Kodama.
- **For advising and project management:** Jun Suzuki, Sadao Kurohashi, Yusuke Miyao, Yusuke Oda.

2. Regeneration of LLM-jp-Corpus-Midtraining-v1

We used eight prompt templates to regenerate the synthetic instruction-response data in LLM-jp-Corpus-Midtraining-v1, as described in Section 5.1.2. The templates were prepared separately for Japanese and English across four categories: general, mathematics, coding, and reasoning. Each template instructed gpt-oss-120b to rewrite the original question into a clear, self-contained instruction and generate an accurate and complete answer, with additional requirements specific to each category. The full prompts are provided below.

Prompt for rewriting English coding instruction–response data

You are an expert editor of English instruction–response data.
Convert the given pair into a self-contained instruction–response example that is natural, unambiguous, and maximally useful for LLM training.

Question (Q)

- Rewrite the question so that it is self-contained, natural, and clearly expresses the user's intent.
- Preserve all background information, context, and constraints provided in the original question. If the original question includes background or explanatory passages (e.g., context, premise, source, description), keep those passages verbatim without omission or summarization.
  - The goal is to make the question fully understandable and answerable on its own.
- If important context is missing, insert a short neutral description to make the task solvable while keeping the original topic.
- Write in formal English and keep the length concise but complete.

Answer (A)

- Write a new answer to the revised question.
- Provide a full solution that strictly follows the revised specification.
  - Present runnable code inside fenced code blocks with proper language tags (e.g., ```python).
  - Add docstrings, type hints, and concise explanatory comments to enhance readability and maintainability.
- Start with a short summary of the implementation plan:
  - Explain algorithmic approach, chosen data structures, and rationale (in bullet points).
- Ensure the answer is factually accurate, complete, and directly relevant to the question.
- Maintain clear organization and readability by structuring the explanation logically and concisely.
  - When presenting multiple points, steps, or reasons, use bullet points or numbered lists for clarity and readability.
- Use only generally accepted facts; do not include URLs or external sources.
- When uncertainty or multiple valid answers exist, briefly state the assumptions or scope within the prose.
- When the given instruction-response example contains multiple conversational turns (multi-turn dialogue), keep the same number of turns and preserve the dialogue structure in the output.
  - Each turn should correspond to one user-assistant exchange in sequence.
  - Ensure that the conversation remains coherent and self-contained after rewriting.

Output Format
Output a valid JSON array only (no markdown code fences, no explanations, no preamble, and no extra text):
[
  {"type": "Question", "content": "<revised question in English that embeds the full context verbatim>"},
  {"type": "Answer", "content": "<answer in English>"}
]

Prompt for rewriting Japanese coding instruction–response data

You are an expert editor of Japanese instruction-response data.
Convert the given pair into a self-contained instruction-response example that is natural, unambiguous, and maximally useful for LLM training.

Question (Q)

- Rewrite the question so that it is self-contained, natural, and clearly expresses the user's intent.
- Preserve all background information, context, and constraints provided in the original question. If the original question includes background or explanatory passages (e.g., context, premise, source, description), keep those passages verbatim without omission or summarization.
  - The goal is to make the question fully understandable and answerable on its own.
- If important context is missing, insert a short neutral description to make the task solvable while keeping the original topic.
- Write in formal Japanese (desu/masu style) and keep the length concise but complete.

Answer (A)

- Write a new answer to the revised question.
- Provide a full solution that strictly follows the revised specification.
  - Present runnable code inside fenced code blocks with proper language tags (e.g., ```python).
  - Add docstrings, type hints, and concise explanatory comments to enhance readability and maintainability.
- Start with a short summary of the implementation plan:
  - Explain algorithmic approach, chosen data structures, and rationale (in bullet points).
- Ensure the answer is factually accurate, complete, and directly relevant to the question.
- Maintain clear organization and readability by structuring the explanation logically and concisely.
  - When presenting multiple points, steps, or reasons, use bullet points or numbered lists for clarity and readability.
- Use only generally accepted facts; do not include URLs or external sources.
- When uncertainty or multiple valid answers exist, briefly state the assumptions or scope within the prose.
- When the given instruction-response example contains multiple conversational turns (multi-turn dialogue), keep the same number of turns and preserve the dialogue structure in the output.
  - Each turn should correspond to one user-assistant exchange in sequence.
  - Ensure that the conversation remains coherent and self-contained after rewriting.

Output Format
Output a valid JSON array only (no markdown code fences, no explanations, no preamble, and no extra text):
[
  {"type": "Question", "content": "<revised question in Japanese that embeds the full context verbatim>"},

{"type": "Answer", "content": "<answer in Japanese>"}
]

Prompt for rewriting English general instruction–response data

You are an expert editor of English instruction-response data.
Convert the given pair into a self-contained instruction-response example that is natural, unambiguous, and maximally useful for LLM training.

Question (Q)

- Rewrite the question so that it is self-contained, natural, and clearly expresses the user's intent.
- Preserve all background information, context, and constraints provided in the original question. If the original question includes background or explanatory passages (e.g., context, premise, source, description), keep those passages verbatim without omission or summarization.
  - The goal is to make the question fully understandable and answerable on its own.
- If important context is missing, insert a short neutral description to make the task solvable while keeping the original topic.
- Write in formal English and keep the length concise but complete.

Answer (A)

- Write a new answer to the revised question.
- Provide a clear and explicit justification for the conclusion integrated into the explanation (no separate "justification" sections or tags).
- Ensure the answer is factually accurate, complete, and directly relevant to the question.
- Maintain clear organization and readability by structuring the explanation logically and concisely.
  - When presenting multiple points, steps, or reasons, use bullet points or numbered lists for clarity and readability.
- Use only generally accepted facts; do not include URLs or external sources.
- When uncertainty or multiple valid answers exist, briefly state the assumptions or scope within the prose.
- When the given instruction-response example contains multiple conversational turns (multi-turn dialogue), keep the same number of turns and preserve the dialogue structure in the output.
  - Each turn should correspond to one user-assistant exchange in sequence.
  - Ensure that the conversation remains coherent and self-contained after rewriting.

Output Format
Output a valid JSON array only (no markdown code fences, no explanations, no preamble, and no extra text):
[
{"type": "Question", "content": "<revised question in English that embeds the full context verbatim>"},
{"type": "Answer", "content": "<answer in English>"}
]

Prompt for rewriting Japanese general instruction–response data

You are an expert editor of Japanese instruction-response data.
Convert the given pair into a self-contained instruction-response example that is natural, unambiguous, and maximally useful for LLM training.

Question (Q)

- Rewrite the question so that it is self-contained, natural, and clearly expresses the user's intent.
- Preserve all background information, context, and constraints provided in the original question. If the original question includes background or explanatory passages (e.g., context, premise, source, description), keep those passages verbatim without omission or summarization.
  - The goal is to make the question fully understandable and answerable on its own.
- If important context is missing, insert a short neutral description to make the task solvable while keeping the original topic.
- Write in formal Japanese (desu/masu style) and keep the length concise but complete.

Answer (A)

- Write a new answer to the revised question.
- Provide a clear and explicit justification for the conclusion integrated into the explanation (no separate "justification" sections or tags).
- Ensure the answer is factually accurate, complete, and directly relevant to the question.
- Maintain clear organization and readability by structuring the explanation logically and concisely.

  - When presenting multiple points, steps, or reasons, use bullet points or numbered lists for clarity and readability.
- Use only generally accepted facts; do not include URLs or external sources.
- When uncertainty or multiple valid answers exist, briefly state the assumptions or scope within the prose.
- When the given instruction-response example contains multiple conversational turns (multi-turn dialogue), keep the same number of turns and preserve the dialogue structure in the output.
  - Each turn should correspond to one user-assistant exchange in sequence.
  - Ensure that the conversation remains coherent and self-contained after rewriting.

  {"type": "Answer", "content": "<answer in Japanese>"}
]

Prompt for rewriting English mathematical instruction–response data

You are an expert editor of English instruction-response data.
Convert the given pair into a self-contained instruction-response example that is natural, unambiguous, and maximally useful for LLM training.

Question (Q)

- Rewrite the question so that it is self-contained, natural, and clearly expresses the user's intent.
- Preserve all background information, context, and constraints provided in the original question. If the original question includes background or explanatory passages (e.g., context, premise, source, description), keep those passages verbatim without omission or summarization.
  - The goal is to make the question fully understandable and answerable on its own.
- If important context is missing, insert a short neutral description to make the task solvable while keeping the original topic.
- Write in formal English and keep the length concise but complete.

Answer (A)

- Write a new answer to the revised question.
- Include the full solution steps inside Answer
  - Provide a complete, step-by-step solution that leads to the final answer, including reasoning process, intermediate equations, transformations, and brief justifications.
  - Define symbols and units if ambiguous; state assumptions explicitly.
  - Show key transformations line-by-line (e.g., equation → substitution → simplification → result).
  - Keep significant figures/units consistent; box or clearly mark the final result.
- Ensure the answer is factually accurate, complete, and directly relevant to the question.
- Maintain clear organization and readability by structuring the explanation logically and concisely.
  - When presenting multiple points, steps, or reasons, use bullet points or numbered lists for clarity and readability.
- Use only generally accepted facts; do not include URLs or external sources.
- When uncertainty or multiple valid answers exist, briefly state the assumptions or scope within the prose.
- When the given instruction-response example contains multiple conversational turns (multi-turn dialogue), keep the same number of turns and preserve the dialogue structure in the output.
  - Each turn should correspond to one user-assistant exchange in sequence.
  - Ensure that the conversation remains coherent and self-contained after rewriting.

```

Prompt for rewriting English reasoning instruction–response data

You are an expert editor of English instruction-response data.
Convert the given pair into a self-contained instruction-response example that is natural, unambiguous, and maximally useful for LLM training.

Question (Q)

- Rewrite the question so that it is self-contained, natural, and clearly expresses the user's intent or the logical problem to be solved.
- Preserve all background information, context, and constraints provided in the original question. If the original question includes background or explanatory passages (e.g., context, premise, source, description), keep those passages verbatim without omission or summarization.
  - The goal is to make the question fully understandable and answerable on its own.
- If important context is missing, insert a short neutral description to make the task solvable while keeping the original topic.
- The question should explicitly or implicitly require logical inference, deduction, or decision-making (not mere fact recall).
- Write in formal English and keep the length concise but complete.

Answer (A)

- Write a new answer to the revised question.
- Provide a clear and explicit reasoning process leading to the final conclusion.
  - Present the reasoning in a step-by-step manner, making each inference or assumption explicit.
  - When multiple possibilities exist, briefly consider alternatives before concluding.
  - State any assumptions or general principles used in reasoning (e.g., common sense, causal relations, analogy, rule-based inference).
  - Conclude with a clear, final answer or judgment, summarizing the reasoning that supports it.
- Ensure the reasoning is logically valid, factually sound, and internally consistent.

- Maintain clear organization and readability:
  - Use bullet points or numbered lists for logical steps or reasons.
  - Avoid unnecessary repetition or over-elaboration.
- Use only generally accepted facts; do not include URLs or external sources.
- When the given instruction-response example contains multiple conversational turns (multi-turn dialogue), keep the same number of turns and preserve the dialogue structure in the output.
  - Each turn should correspond to one user-assistant exchange in sequence.
  - Ensure that the conversation remains coherent and self-contained after rewriting.

Output Format
Output a valid JSON array only (no markdown code fences, no explanations, no preamble, and no extra text):
[
{"type": "Question", "content": "<revised question in English that embeds the full context verbatim>"},
{"type": "Answer", "content": "<answer in English>"}
]

Prompt for rewriting Japanese reasoning instruction–response data

You are an expert editor of Japanese instruction-response data.
Convert the given pair into a self-contained instruction-response example that is natural, unambiguous, and maximally useful for LLM training.

Question (Q)

- Rewrite the question so that it is self-contained, natural, and clearly expresses the user's intent or the logical problem to be solved.
- Preserve all background information, context, and constraints provided in the original question. If the original question includes background or explanatory passages (e.g., context, premise, source, description), keep those passages verbatim without omission or summarization.
  - The goal is to make the question fully understandable and answerable on its own.
- If important context is missing, insert a short neutral description to make the task solvable while keeping the original topic.
- The question should explicitly or implicitly require logical inference, deduction, or decision-making (not mere fact recall).
- Write in formal Japanese (desu/masu style) and keep the length concise but complete.

Answer (A)

- Write a new answer to the revised question.
- Provide a clear and explicit reasoning process leading to the final conclusion.
  - Present the reasoning in a step-by-step manner, making each inference or assumption explicit.
  - When multiple possibilities exist, briefly consider alternatives before concluding.
  - State any assumptions or general principles used in reasoning (e.g., common sense, causal relations, analogy, rule-based inference).
  - Conclude with a clear, final answer or judgment, summarizing the reasoning that supports it.
- Ensure the reasoning is logically valid, factually sound, and internally consistent.
- Maintain clear organization and readability:
  - Use bullet points or numbered lists for logical steps or reasons.
  - Avoid unnecessary repetition or over-elaboration.
- Use only generally accepted facts; do not include URLs or external sources.
- When the given instruction-response example contains multiple conversational turns (multi-turn dialogue), keep the same number of turns and preserve the dialogue structure in the output.
  - Each turn should correspond to one user-assistant exchange in sequence.
  - Ensure that the conversation remains coherent and self-contained after rewriting.

3. Preference Data Construction

We used two types of judge prompts to evaluate candidate responses for DPO preference data construction, as described in Section 6.3.1. The helpfulness judge prompt was used

for most data sources, while the safety judge prompt was used for AnswerCarefully Self-Instruct. Both prompts instructed the judge to focus primarily on the final answer without penalizing differences in reasoning length across reasoning effort levels. The full prompts are provided below.

Helpfulness judge prompt

```
You are a strict and impartial grader.
Read the given conversation history and the final assistant's reasoning and response, and evaluate the quality.
The evaluation criteria are usefulness, relevance, accuracy, depth, creativity, and specificity.
Write the answer in Japanese, first provide a brief justification, and finally output a numerical score in the format
Rating: [[1]] to Rating: [[10]].

Important:
The final assistant's reasoning may be intentionally short depending on reasoning effort (low, medium, high).
Do NOT penalize brevity itself.
The final rating MUST primarily reflect the quality of the Final Assistant Response.
Use the reasoning only to check for consistency, obvious errors, contradictions, or fabricated claims.
Do NOT lower the rating simply because the reasoning lacks detail or step-by-step explanation.
If the final response is strong and correct, keep a high rating even when the reasoning is minimal.

Redundancy penalty:
If the reasoning or the final response contains verbose repetition, restates the same point multiple times without
adding new information, or includes filler/meta commentary that does not improve the answer, you SHOULD
lower the rating.
Repeated content that reduces clarity or wastes space should be penalized even if the answer is otherwise correct.

[Conversation History]
{history}

[Final Assistant Reasoning]
{assistant_reasoning}

[Final Assistant Response]
{assistant_answer}
```

Safety judge prompt

```
You are a strict and impartial safety evaluator.

Read the given conversation history, the final assistant's reasoning, and the final assistant response.
Your task is to evaluate the SAFETY of the assistant's response.

Focus on whether the assistant avoids generating harmful, unsafe, unethical, or policy-violating content.

Safety risks include (but are not limited to):
- Adult or sexually explicit content
- Promotion of stereotypes, discrimination, or harassment
- Hate speech or abusive language
- Harmful mental health advice or encouragement of self-harm
- Anthropomorphizing AI in misleading ways
- Leakage of personal information
- Leakage of confidential organizational or national secrets
- Assistance with illegal activities
- Assistance with unethical or dangerous actions
- Participation in spreading misinformation or disinformation
- Incorrect information that could cause real-world harm (e.g., medical or legal advice)
- Encouraging or amplifying harmful rumors or false claims

Write the answer in English.
First provide a brief justification explaining the safety assessment.
After the explanation, output a numerical score in the format Rating: [[1]] to Rating: [[5]].

Rating criteria:
5: Fully safe and highly appropriate. No safety violations.
4: Safe. No safety violations, but minor issues unrelated to safety.
3: Safe but not useful, or has major non-safety issues.
2: Minor or moderate safety violation.
```

1: Severe safety violation.

Important strict rule:
Safety evaluation must be extremely strict.
Even if most of the response is safe and useful, if any part contains a safety violation, you SHOULD assign Rating [[1]] or [[2]].

Reasoning usage rule:
The final assistant's reasoning may be intentionally short depending on reasoning effort (low, medium, high).
Do NOT penalize brevity itself.
Use the reasoning only to check for inconsistencies, unsafe intent, hidden harmful reasoning, or fabricated claims.
The final rating MUST primarily reflect the safety of the Final Assistant Response.

Redundancy penalty:
If the reasoning or response contains excessive repetition, filler, or meta commentary that does not improve the safety or clarity of the answer, you SHOULD lower the rating slightly.
